

Programming With C

Language ?

- Natural
- Formal
- Context Free
- Programming Language

Levels Of Programming Languages

1 low level : machine language , assembly language

2 Middle level languages : Fortran , Cobol , pascal , C

3 High level languages : SQL, Prolog , Lisp ,

Compilers Vs Interpreters

Generation Of Programming Languages

History of Programming Languages

- **1940s: Von Neumann**
- **1950s: First Programming Language**
- **1960s: Basic Programming (B Language)**
- **1970s: C Language(Simplicity, Abstraction,Study)
by Dennis Ritchie**
- **1975s: C++ Language(object Oriented, Logic Programming)
by Benjamin Strawstroup**
- **1980s:GUI Programming**
- **1990s: Visual Basic by Microsoft and Java by James Gosling
at Sun Microsystems**
- **1992: Platform Indepedent Language(Java)**
- **1999: Dot Net Platform By Microsoft**
- **2000s: Scripting, Web Programming Like PHP,Asp.net,Javascript,VBScript**
- **2010s: Parallel Computing, Concurrency**

History Of C

Developed in 1972 at AT&T bell labs

- GPPL
- Data Types
- UNIX
- ANSI American national standard Institute
- ASCII

Advantages of C

- Why C
- System programming
- Networking
- Virus and Anti virus
- Fire walls
- Compiler Designing
- Middle level Programming (benefits of both)
- No competitor at that time

- Data Types
- Data structures
- Functions, Structures and unions
- For Loop
- Do While Loop
- Switch Case
- Pointers
- File handling
- Addressing
- OS designing Algorithms
- Loaders and Linkers
- ETC

- Steps to learn Natural Language
 - Alphabets
 - Words
 - Sentences
 - Paragraphs
-
- Steps to learn C language
 - Alphabets , digits , special symbols (ascii – 256)
 - Constants , variables , keywords
 - Instructions
 - Program

Files in C

- .c Text file
- .Bak file
- .Obj File Compiled file Object code file Machine understandable
- .Exe Executable File

- Variables which change their values
- $A=9$, $B=6$, $C=7$: $A=b+c$;
- Constants in C

Data type

```
graph TD; A[Data type] --> B[Primitive]; A --> C[Derivied]; A --> D[User defined]; B --> B1[char]; B --> B2[int]; B --> B3[float]; B --> B4[double]; B --> B5[void]; C --> C1[Array]; C --> C2[Pointer]; C --> C3[Function]; D --> D1[enum]; D --> D2[Structure]; D --> D3[Union];
```

Primitive

char

int

float

double

void

Derivied

Array

Pointer

Function

User defined

enum

Structure

Union

Basic Types of Constants

Data type	Size(bytes)	Range	Format String
char	1	-128 to 127	%c
unsigned char	1	0 to 255	%c
short	2	-32,768 to 32,767	%d
unsigned short	2	0 to 65535	%u
int	2	32,768 to 32,767	%d
unsigned int	2	0 to 65535	%u
long	4	-2147483648 to +2147483647	%ld
Unsinged long	4	0 to 4294967295	%lu
float	4	-3.4e-38 to +3.4e-38	%f
double	8	1.7 e-308 to 1.7 e+308	%lf
long double	10	3.4 e-4932 to 1.1 e+4932	%lf

Keywords in C

auto	double	int	struct
break	else	long	switch
case	enum	register	typedef
char	extern	return	union
continue	for	signed	void
do	if	static	while
default	goto	sizeof	Volatile
const	float	short	Unsigned

Structure of C Program

<i>Header</i>	<code>#include <stdio.h></code>
<i>main()</i>	<code>int main() {</code>
<i>Variable declaration</i>	<code>int a = 10;</code>
<i>Body</i>	<code>printf("%d ", a);</code>
<i>Return</i>	<code>return 0; }</code>

Structure of a C program

```
#include <stdio.h>
void main (void)
{
    printf("\nHello World\n");
}
```

Preprocessor directive (header file)

Program statement

```
#include <stdio.h>
#define VALUE 10
int global_var;
void main (void)
{
    /* This is the beginning of the program */
    int local_var;
    local_var = 5;
    global_var = local_var + VALUE;
    printf("Total sum is: %d\n", global_var); // Print out the result
}
```

Preprocessor directive

Global variable declaration

Local variable declaration

Variable definition

Operators in C

Operators in C		
Operation Type	Operator's Type	Operators
Unary Operators	increment, Decrement Operators	++, --
	Arithmetic Operators	+, -, *, /, %
Binary Operators	Logical Operators	&&, , !
	Relational Operators	<, <=, >, >=, ==, !=
	Bit-wise Operators	&, , <<, >>, ~, ^
	Assignment Operators	=, +=, -=, *=, /=, %=
Ternary Operator	Ternary or Conditional Operator	? :

Input Output in C

- `Printf(" ");`
- `Printf(" ",variable);`
- `Scanf(" % .... " , &variable);`
- `getchar();`

Decision making and Branching

- If
- Else
- Nested if
- Nested if else

Conditional Statement

If-else

Switch

if

```
if( condition )  
{  
    //true  
}
```

if-else

```
if( condition )  
{  
    //true  
}  
else  
{  
    //false  
}
```

if-else if

```
if( condition 1 )  
{  
    //true  
}  
else if( condition 2 )  
{  
    //true  
}  
else  
{  
}
```

Nested if

```
if( condition 1 )  
{  
    if( condition )  
    {  
    }  
    else  
    {  
    }  
}  
else  
{  
    if( condition )  
    {  
    }  
    else  
    {  
    }  
}
```

```
switch( expression )  
{  
    case 1:  
        break;  
    case 2:  
        break;  
    case 3:  
        break;  
    default;  
}
```

```
#include <stdio.h>
int main() {
    int num = 8; 1
    2 switch (num) {
        case 7:
            printf("Value is 7");
            break;
        case 8: 3
            printf("Value is 8");
            break;
        case 9:
            printf("Value is 9");
            break;
        default:
            printf("Out of range");
            break;
    }
    return 0;
}
```

Loops in C and their advantages

Loops

Entry Controlled

for

```
for( initialization ; condition; updation)
{
}
```

while

```
while( condition )
{
}
```

Exit Controlled

do-while

```
do
{
}while( condition )
```

do-while Loop

While

```
int i = 0;  
while(i > 0)  
{  
    printf("%d", i);  
    i--;  
}
```

do-While

```
int i = 0;  
do  
{  
    printf("%d", i);  
    i--;  
} while(i > 0);
```

“For” loop

```
for( a = 5; a <= 10; a++ )
```

Initilization

Condition

Increment (++)
or
Decrement (--)

Sitesbay.com

- Break loop

- out of a **loop**.

- ```
for (i = 0; i < 10; i++) {
 if (i == 4) {
 break;
 }
 printf("%d\n", i);
}
```

- Continue loop

breaks one iteration

```
for (i = 0; i < 10; i++) {
 if (i == 4) {
 continue;
 }
 printf("%d\n", i);
}
```

# Arrays in C

## Array Declaration in C

`int a[3];`

|      |     |       |
|------|-----|-------|
| 2192 | 451 | 13918 |
|------|-----|-------|

`int a[3]={1, 2, 3};`

|   |   |   |

|       | 2 | 9     | 10 | 11 | 12 |

# Strings

## Initialization of strings

- In C, string can be initialized in a number of different ways.
- For convenience and ease, both initialization and declaration are done in the same step.

```
char c[] = "abcd";
```

OR,

```
char c[50] = "abcd";
```

OR,

```
char c[] = {'a', 'b', 'c', 'd', '\0'};
```

OR,

```
char c[5] = {'a', 'b', 'c', 'd', '\0'};
```

|   |   |   |   |    |
|---|---|---|---|----|
| a | b | c | d | \0 |
|---|---|---|---|----|

# String in c

## Important String Functions

1. `strlen()`
2. `strupr()`
3. `strlwr()`
4. `strrev()`
5. `strcpy()`
6. `strcat()`
7. `strcmp()`

**strlen** - Finds out the length of a string

**strlwr** - It converts a string to lowercase

**strupr** - It converts a string to uppercase

**strcat** - It appends one string at the end of another

**strncat** - It appends first n characters of a string at the end of another.

**strcpy** - Use it for Copying a string into another

**strncpy** - It copies first n characters of one string into another

**strcmp** - It compares two strings

**strncmp** - It compares first n characters of two strings

**strcmpi** - It compares two strings without regard to case ("i" denotes that this function ignores case)

**stricmp** - It compares two strings without regard to case (identical to strcmpi)

**strnicmp** - It compares first n characters of two strings, Its not case sensitive

**strdup** - Used for Duplicating a string

**strchr** - Finds out first occurrence of a given character in a string

**strrchr** - Finds out last occurrence of a given character in a string

**strstr** - Finds first occurrence of a given string in another string

**strset** - It sets all characters of string to a given character

**strnset** - It sets first n characters of a string to a given character

**strrev** - It Reverses a string

# Structure in C

- A structure is a user-defined data type available in C that allows to combining data items of different kinds. Structures are used to represent a record.

```
struct employee
{
 int id;
 char name[50];
 string department;
 string email;
};
```

```
struct student
{
 int rollno;
 char name[50];
 string phone;
};
```

A **Union** is a user-defined data type. It is just like the structure except that all of its members start at the same location in memory. The union combines various objects of different data types in the same memory location. A user can define a union with many members, but at any given time, only one member can hold a value. The storage space allocated for the union variable is equal to the total space required by the largest data member of the union.

```
union abc
{
 int a;
 char b;
}var;
int main()
{
 var.a = 66;
 printf("\n a = %d", var.a);
 printf("\n b = %d", var.b);
}
```

- **Similarities between Structure and Union**

1. Both are user-defined data types used to store data of different types as a single unit.
2. Their members can be objects of any type, including other structures and unions or arrays. A member can also consist of a bit field.
3. Both structures and unions support only assignment = and sizeof operators. The two structures or unions in the assignment must have the same members and member types.
4. A structure or a union can be passed by value to functions and returned by value by functions. The argument must have the same type as the function parameter. A structure or union is passed by value just like a scalar variable as a corresponding parameter.
5. ‘.’ operator is used for accessing members.

|                           | STRUCTURE                                                                                                                                                                                    | UNION                                                                                                                                                                                         |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keyword                   | The keyword <b>struct</b> is used to define a structure                                                                                                                                      | The keyword <b>union</b> is used to define a union.                                                                                                                                           |
| Size                      | When a variable is associated with a structure, the compiler allocates the memory for each member. The size of structure is <b>greater than or equal to the sum of sizes of its members.</b> | when a variable is associated with a union, the compiler allocates the memory by considering the size of the largest memory. So, size of <b>union is equal to the size of largest member.</b> |
| Memory                    | Each member within a structure is assigned unique storage area of location.                                                                                                                  | Memory allocated is shared by individual members of union.                                                                                                                                    |
| Value Altering            | Altering the value of a member will not affect other members of the structure.                                                                                                               | Altering the value of any of the member will alter other member values.                                                                                                                       |
| Accessing members         | Individual member can be accessed at a time.                                                                                                                                                 | Only one member can be accessed at a time.                                                                                                                                                    |
| Initialization of Members | Several members of a structure can initialize at once.                                                                                                                                       | Only the first member of a union can be initialized.                                                                                                                                          |

# Pointers in C

- The pointer in C language is **a variable which stores the address of another variable**. This variable can be of type int, char, array, function, or any other pointer. The size of the pointer depends on the architecture. However, in 32-bit architecture the size of a pointer is 2 byte.

# Why are Pointers Used ?

- **To return more than one value from a function**
- **To pass arrays & strings more conveniently from one function to another**
- **To manipulate arrays more easily by moving pointers to them, Instead of moving the arrays themselves**
- **To allocate memory and access it (Dynamic Memory Allocation)**
- **To create complex data structures such as Linked List, Where one data structure must contain references to other data structures**

# Memory Management In C

| Function          | Task                                                                                                                         |
|-------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>malloc( )</b>  | Allocate request size of bytes & return a pointer to the first byte of the allocated space. And contains garbage values.     |
| <b>calloc( )</b>  | Allocate space for an array of elements, initialize them to zero and returns a pointer to the first byte of allocated space. |
| <b>realloc( )</b> | Modify the size of previously allocated space.                                                                               |
| <b>free( )</b>    | Free the previously allocated space.                                                                                         |

# File handling in C

| File operation                          | Declaration & Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>fopen() - To open a file</b>         | <p>Declaration: <code>FILE *fopen (const char *filename, const char *mode)</code><br/>fopen() function is used to open a file to perform operations such as reading, writing etc. In a C program, we declare a file pointer and use fopen() as below. fopen() function creates a new file if the mentioned file name does not exist.</p> <pre>FILE *fp;<br/>fp=fopen ("filename", "'mode");</pre> <p>Where,<br/>fp - file pointer to the data type "FILE".<br/>filename - the actual file name with full path of the file.<br/>mode - refers to the operation that will be performed on the file. Example: r, w, a, r+, w+ and a+. Please refer below the description for these mode of operations.</p> |
| <b>fclose() - To close a file</b>       | <p>Declaration: <code>int fclose(FILE *fp);</code><br/>fclose() function closes the file that is being pointed by file pointer fp. In a C program, we close a file as below.</p> <pre>fclose (fp);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>fgets() - To read a file</b>         | <p>Declaration: <code>char *fgets(char *string, int n, FILE *fp)</code><br/>fgets function is used to read a file line by line. In a C program, we use fgets function as below.</p> <pre>fgets (buffer, size, fp);</pre> <p>where,<br/>buffer - buffer to put the data in.<br/>size - size of the buffer<br/>fp - file pointer</p>                                                                                                                                                                                                                                                                                                                                                                      |
| <b>fprintf() - To write into a file</b> | <p>Declaration:<br/><code>int fprintf(FILE *fp, const char *format, ...);</code> fprintf() function writes string into a file pointed by fp. In a C program, we write string into a file as below. fprintf (fp, "some data"); or<br/>fprintf (fp, "text %d", variable_name);</p>                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Function

## description

|           |                                           |
|-----------|-------------------------------------------|
| fopen()   | create a new file or open a existing file |
| fclose()  | closes a file                             |
| getc()    | reads a character from a file             |
| putc()    | writes a character to a file              |
| fscanf()  | reads a set of data from a file           |
| fprintf() | writes a set of data to a file            |
| getw()    | reads a integer from a file               |
| putw()    | writes a integer to a file                |
| fseek()   | set the position to desire point          |
| ftell()   | gives current position in the file        |
| rewind()  | set the position to the begining point    |
